1 INTRODUCTION

This topic will show you how to test the generated Web API endpoints.

2 SWAGGER INDEX PAGE

When you run the generated *Web Application* and *Web API* projects by pressing F5 in Visual Studio, two browsers are launched, one for each of the projects respective. The *Web API* project will launch the *Swagger Index Page* by default, shown below. The *Swagger Index Page* contains *Web API Endpoints* for each of the database table that you generated code for.

2.1 WEB API ENDPOINTS?

In the example above, the **CategoryAPI** which is derived from the *Categories* table in the *Northwind* database shows the *Web API Endpoints* available for the *Categories* table. If you move further down the web page you'll see other Web APIs such as *CustomerAPI*, *CustomerAPI*, *EmployeeAPI*, *ProductAPI*, etc, where each also have their own *Web API Endpoints* just like the *CategoryAPI*.

2.2 WEB API SCHEMA?

Further down the web page you'll notice that a *Schema* for each *Web API* is shown. The *Schema* shows the structure of the respective Web API. This is how we know how to interact (what type of data to pass) with the *Web API Endpoints*. For example, the **CategoryAPI** has 3 fields, *categoryID*, *categoryName*, and *description*. Each of these fields shows their type and other restrictions.

- categoryID**: int32 (required)
- categoryName**: string (required), maximum length 15 characters.
- description**: string, no maximum length (nullable – not required)

For most parts the *Schema's Fields* are direct reflection of the database table fields it represents. For example, the *Category Schema's Fields* are directly related to the *Categories Database Table Fields*.

Schemas

```

Category {
  categoryID      integer($int32)
  categoryName*   string
                  maxLength: 15
                  minLength: 0
  description     string
                  nullable: true
}

```

Database Table

dbo.Categories

Columns

- CategoryID (PK, int, not null)
- CategoryName (nvarchar(15), not null)
- Description (ntext, null)

Some *Schemas* have more fields in them than the *Database Table* it represents, like the *Product Schema*. When interacting with the **ProductAPI Schema** all that is required are the *Fields* available in the *Products Database Table*. We will show this later when we try to insert a record in the *Products Table*.

```

Product {
  productID      integer($int32)
  productName*   string
                  maxLength: 40
                  minLength: 0
  supplierID     integer($int32)
                  nullable: true
  categoryID     integer($int32)
                  nullable: true
  quantityPerUnit string
                  maxLength: 20
                  minLength: 0
                  nullable: true
  unitPrice      number($double)
                  pattern: [-+]?[0-9]*\.[0-9]?
                  nullable: true
  unitsInStock   integer($int32)
                  maximum: 32767
                  minimum: -32768
                  nullable: true
  unitsInStockHidden string
                  maximum: 32767
                  minimum: -32768
                  pattern: ([0-9]*)
                  nullable: true
  unitsOnOrder   integer($int32)
                  maximum: 32767
                  minimum: -32768
                  nullable: true
  unitsOnOrderHidden string
                  maximum: 32767
                  minimum: -32768
                  pattern: ([0-9]*)
                  nullable: true
  reorderLevel   integer($int32)
                  maximum: 32767
                  minimum: -32768
                  nullable: true
  reorderLevelHidden string
                  maximum: 32767
                  minimum: -32768
                  pattern: ([0-9]*)
                  nullable: true
  discontinued*  boolean
  supplier       Supplier > {...}
  category       Category > {...}
}

```

Database Table

dbo.Products

Columns

- ProductID (PK, int, not null)
- ProductName (nvarchar(40), not null)
- SupplierID (FK, int, null)
- CategoryID (FK, int, null)
- QuantityPerUnit (nvarchar(20), null)
- UnitPrice (money, null)
- UnitsInStock (smallint, null)
- UnitsOnOrder (smallint, null)
- ReorderLevel (smallint, null)
- Discontinued (bit, not null)

3 TESTING WEB API ENDPOINTS

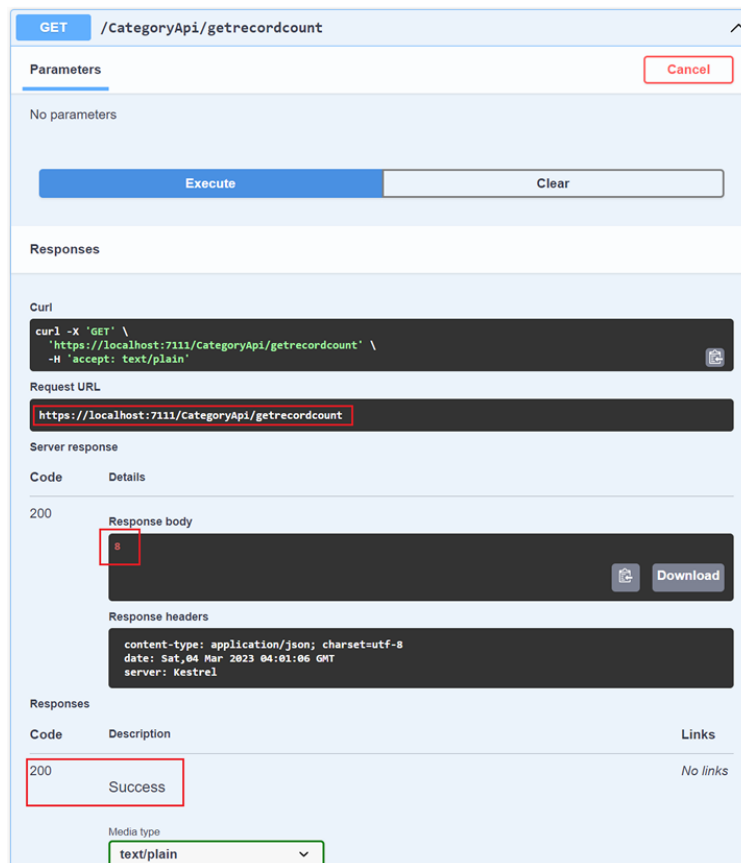

As developers this is probably self-explanatory. However, we will show how to test some of these endpoints.

3.1 GET RECORD COUNT ENDPOINT

Click the */CategoryApi/getrecordcount*. And then click the *Try it out* button. And then click the *Execute* button.

The result will show the *Request URL*, you can use this in your code to call this endpoint. Also shows the *Response Body* **8** (*getrecordcount* endpoint simply returns a number), which is the *total number of records* in the *Categories* database table. And the *Response Code*, *200* means *Success* (the web API call was successful).

3.2 SELECT, SKIP, AND TAKE ENDPOINT

Now try the `/CategoryApi/selectskipandtake` endpoint. Click the *Try it out* button. This endpoint requires 4 parameters:

1. **sidx** – Field to sort.
2. **sord** – Sort order. *asc* or *blank* (nothing) for ascending order, and *desc* for descending order.
3. **rows** – Number of rows you want returned.
4. **page** – based on the number of rows you're requesting, there may be several pages to return, this is the *page number* you want returned. For example, if there are 37 records in the *Categories* database table, and the *rows* you requested is 5, then there will be 7 pages, you can request any number from 1 to 7.

Name	Description
idx string (query)	CategoryName
sord string (query)	sord
page integer(\$int32) (query)	1
rows integer(\$int32) (query)	5

The *Response* shows a *Code 200* (success), *5 records* returned (in descending order by *CategoryName*) in *json* format.

Request URL

`https://localhost:7111/CategoryApi/selectskipandtake?idx=CategoryName&page=1&rows=5`

Server response

Code	Details
200	Response body

```
[
  {
    "categoryID": 1,
    "categoryName": "Beverages",
    "description": "Soft drinks, coffees, teas, beers, and ales"
  },
  {
    "categoryID": 2,
    "categoryName": "Condiments",
    "description": "Sweet and savory sauces, relishes, spreads, and seasonings"
  },
  {
    "categoryID": 3,
    "categoryName": "Confections",
    "description": "Desserts, candies, and sweet breads"
  },
  {
    "categoryID": 4,
    "categoryName": "Dairy Products",
    "description": "Cheeses"
  },
  {
    "categoryID": 5,
    "categoryName": "Grains/Cereals",
    "description": "Breads, crackers, pasta, and cereal"
  }
]
```

Response headers

```
content-type: application/json; charset=utf-8
date: Sat, 04 Mar 2023 04:27:38 GMT
server: Kestrel
```

3.3 INSERT ENDPOINT

Under the *ProductAPI*, click the ***/ProductApi/insert*** endpoint. Click the *Try it out* button. This endpoint only has 1 parameter: *isForListInlineOrListCrud* parameter. This parameter is used in the web application, so we don't really care about this one for this example.

What's more important is the *Request body*. Because the operation is a POST, we need to pass the parameters via the *Request body*, and it's showing here that it's expecting a json formatted body. It's also showing the type of each parameter.

Note: for a more detailed information on the requirements for each of the parameters in the *Request Body*, please refer to the respective *Schema* of the *Web API* as shown in 2.2.

POST

/ProductApi/insert

Parameters

Cancel

Name	Description
isForListInlineOrListCrud	false
boolean	
(query)	

Request body

application/json

```
{
  "productID": 0,
  "productName": "string",
  "supplierID": 0,
  "categoryID": 0,
  "quantityPerUnit": "string",
  "unitPrice": 0,
  "unitsInStock": 32767,
  "unitsInStockHidden": "string",
  "unitsOnOrder": 32767,
  "unitsOnOrderHidden": "string",
  "reorderLevel": 32767,
  "reorderLevelHidden": "string",
  "discontinued": true,
  "supplier": {
    "supplierID": 0,
    "companyName": "string",
    "contactName": "string",
    "contactTitle": "string",
    "address": "string",
    "city": "string",
    "region1": "string",
    "postalCode": "string",
    "country": "string",
    "phone": "string",
    "fax": "string",
    "homePage": "string"
  },
  "category": {
    "categoryID": 0,
    "categoryName": "string",
    "description": "string"
  }
}
```

Like discussed in Page 4, under the *Web API Schema* section, some of these fields are not required. We need to remove some of the parameters that are not required and change the values we want inserted in the *Products* table, and then click *Execute*.

POST /ProductApi/insert

Parameters

Cancel

Reset

Name

Description

isForListInlineOrListCrud

false

boolean

(query)

Request body

application/json

```
{
  "productID": 1,
  "productName": "My Product",
  "supplierID": 1,
  "categoryID": 2,
  "quantityPerUnit": "10 items per unit",
  "unitPrice": 20,
  "unitsInStock": 30,
  "unitsOnOrder": 100,
  "reorderLevel": 100,
  "discontinued": false
}
```

Execute

Clear

Responses

Curl

```
curl -X 'POST' \
  'https://localhost:7111/ProductApi/insert?isForListInlineOrListCrud=false' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json' \
  -d '{
    "productID": 1,
    "productName": "My Product",
    "supplierID": 1,
    "categoryID": 2,
    "quantityPerUnit": "10 items per unit",
    "unitPrice": 20,
    "unitsInStock": 30,
    "unitsOnOrder": 100,
    "reorderLevel": 100,
    "discontinued": false
  }'
```

Request URL

https://localhost:7111/ProductApi/insert?isForListInlineOrListCrud=false

Server response

Code

Details

200

Response headers

We got a *Server Response Code 200*, which means *Success*, this record has been inserted in the database.

Note: Although the *productID* was sent on this Web API post, it is disregard by the Data Repository code on the backend because it is an *Identity Field* on the database, which means the database will generate the *productID* on the fly everytime we add a new record on the *Products* table in the database.

You can read end-to-end tutorials on more subjects on using AspCoreGen 6.0 MVC Professional Plus that came with your purchase. These tutorials are available to customers and are included in a link on your invoice when you purchase AspCoreGen 6.0 MVC Professional. Download example shown here at: <https://junnark.com/CustomProjectSamples/acg6mvc/StoredProcWa.zip>

Note: Some features shown here are not available in the Express Edition. The code in this tutorial is available for download for paying customers only, please email us at Software Support for more information.

End of tutorial.
